

Dictionaries and records

Project: Python readiness portfolio

1. Your mission

Your learning target

I can read and update named dictionary fields.

I can connect a record to a function call.

I can distinguish missing fields from zero values.

Remember before reading

Close your notes first. A rough first answer helps us choose the right starting point; it is not a score for your ability.

Without opening the old lesson, explain one key idea from Return values and local state. Give an example and a mistake that the idea helps you avoid.

Without opening the old lesson, explain one key idea from Lists and indexing. Give an example and a mistake that the idea helps you avoid.

Without opening the old lesson, explain one key idea from Boolean conditions. Give an example and a mistake that the idea helps you avoid.

After trying, check the relevant lesson or ask your teacher. Change the part of your explanation that the evidence shows was wrong.

This week you will practise:

Read and update named dictionary fields

Connect a record to a function call

Distinguish missing fields from zero values

Retrieve what you already know

What does `remaining(8, 3)` return when its body returns `capacity - used`?

My starting explanation

This week's end goal

Trace dictionaries and records and explain the changed program before running it.

2. Notice the evidence

A fictional cupboard record has a name, capacity and used count. A list asks us to remember positions. Named fields make the intended meaning visible. Our schema requires name as text and capacity and used as nonnegative integers, with used no greater than capacity.

List the given facts and one fact that is not supplied.

3. See how it works

```
cupboard = {"name": "Blue", "capacity": 12, "used": 4}

def remaining(capacity, used):
    return capacity - used

print(remaining(cupboard["capacity"], cupboard["used"]))

cupboard["used"] = 6

print(remaining(cupboard["capacity"], cupboard["used"]))
```

Follow the evidence

Step or case · Evidence · Meaning

Step or case: Read used

Evidence: 4

Meaning: $12 - 4 = 8$

Step or case: Update used

Evidence: 6

Meaning: $12 - 6 = 6$

Read each row from left to right and connect the evidence to the stated rule.

Square brackets look up the value for a key. The quoted key "used" is text; its value is an integer. Assigning to an existing key replaces that field. Other fields remain the same. Dictionary syntax does not enforce our schema: the programmer must check it.

Connect the picture and the explanation

Point to the input, the deciding step and the result in this week's visual. Explain the same step in ordinary words. A picture helps when you can say what each part represents.

4. Compare the cases

Compare a familiar case with a changed case

Change the Red record used to 9. State remaining spaces and whether capacity changes.

Keep the procedure fixed. Explain what changed in the inputs and result.

Change one thing in the pictured case

Change: Add the field price with value 0.

Prediction: The price lookup now returns 0 instead of None.

Reason: A recorded zero is a present value, whereas the earlier lookup had no field.

5. Words that unlock the idea

Word · Meaning

Word: Dictionary

Meaning: A mapping from unique keys to values

Word: Key

Meaning: A name used to look up a value

Word: Record

Meaning: Related fields describing one item

Word: KeyError

Meaning: The error from looking up an absent dictionary key

Use two terms to explain a step in this week's example.

6. Follow a worked example

Set used to 12. Predict the returned spaces. Does a used value of 0 mean the field is missing?

Learn from the worked case

Cover the result before checking it. Say what is given, choose the procedure, and follow one step at a time. Then uncover the result and explain your first mismatch. Ask why a step is allowed, not only what number

it produces.

A pictorial worked case: Dictionaries and records

A zero field is still present. A dictionary record describes a shelf. The program distinguishes missing data from an actual zero.

The facts we will use

Python 3: shelf={"count":0,"name":"Atlas"}; print(shelf["count"]); print(shelf.get("price")); print("count" in shelf).

AI ACADEMY / PYTHON-BRIDGE/10

Dictionaries and records

Start with the supplied facts

Follow each arrow. Ask which fact allows the next step.

1. Read a stored field

count exists with numeric value 0.

2. Read an absent field

get("price") returns None because price is missing and no default was supplied.

3. Test key membership

"count" in shelf is True even though its value is zero.

CHANGE ONE THING

Add the field price with value 0.

Explain the changed result using the matching lesson.

Read the picture one step at a time

Step · What happens and why

Step: 1. Read a stored field

What happens and why: count exists with numeric value 0.

Step: 2. Read an absent field

What happens and why: get("price") returns None because price is missing and no default was supplied.

Step: 3. Test key membership

What happens and why: "count" in shelf is True even though its value is zero.

Match each pictured step to the supplied facts. This is a worked teaching case, not an independent assessment.

Why this result follows

Dictionary keys name fields. Presence is different from truthiness of a value; a measured zero should not be discarded as if the field were absent.

What this example does not establish

None is also a possible explicitly stored value; real record contracts must define how missing and null values are represented.

Read the labelled picture: Predict all three original outputs. Explain the difference between count=0 and missing price, then predict the lookup after price=0 is added.

Change one thing: Add the field price with value 0. Predict the result before checking the explanation. What remains the same?

7. Find and repair a mistake

cupboard["Used"] raises KeyError here because keys are case sensitive. Correct it to "used". Adding a new field called "Used" would create a second key and leave the original unchanged; it would not repair the intended lookup.

Locate the earliest unsupported step

The code reads record["Used"] from the Red record. Explain the error and repair it without adding a field.

State one repair and the checks you would rerun.

8. Practise together

For {"name": "Red", "capacity": 9, "used": 2}, state the keys, value of used and remaining spaces.

Set used to 12. Predict the returned spaces. Does a used value of 0 mean the field is missing?

Explain your prediction to a partner before comparing results.

Practise with less help: Trace an update

Use workbook W2 for the connected example “Dictionaries and records”. First fill the input and rule boxes. Try the middle steps before asking for a hint. After a hint, try the next step yourself.

Plan · Do · Check

Plan: What is given? Which rule or procedure applies?

Do: Record each intermediate step.

Check: Does the result follow? What remains unknown?

Explain your trace to a partner. Your partner points to one step to check. Swap roles on the next case. Each person writes their own explanation.

Check your reasoning

Use the worked case for Dictionaries and records. Proposed explanation: "A successful run proves the conclusion". Decide whether this explanation is supported. Point to the step or supplied fact that decides; explain your repair if needed.

Answer on your own before discussion. If you are unsure, say which step you need help with.

Explain the picture

Predict all three original outputs. Explain the difference between count=0 and missing price, then predict the lookup after price=0 is added.

My explanation using a pictured step and the given facts

This is supported practice. Keep the separately named independent case for an attempt before feedback.

9. Run the investigation

Predict, investigate and preserve the evidence

Change the Red record used to 9. State remaining spaces and whether capacity changes.

```
cupboard = {"name": "Blue", "capacity": 12, "used": 4}

def remaining(capacity, used):
    return capacity - used

print(remaining(cupboard["capacity"], cupboard["used"]))

cupboard["used"] = 6

print(remaining(cupboard["capacity"], cupboard["used"]))
```

Record · Your evidence

Record: Given input and fixed rule

Your evidence: _____

Record: Prediction before checking

Your evidence: _____

Record: Actual result, or “not run”

Your evidence: _____

Record: First mismatch and one explanation

Your evidence: _____

Record: Boundary or missing input and expected response

Your evidence: _____

On paper, trace the supplied procedure. If code is provided, predict before running it in a local practice file. Never write an expected answer as though it were an observed run.

Plan → try → check

Before trying: what do I expect, and why? While trying: which step could first go wrong? Afterwards: what did I actually observe, and what should change? Keep “not run” if you only traced the procedure.

10. Build your understanding

Explain → apply → challenge

For {"name": "Red", "capacity": 9, "used": 2}, state the keys, value of used and remaining spaces.

The code reads record["Used"] from the Red record. Explain the error and repair it without adding a field.

A record has capacity 3 and used 4. It gives -1 spaces without an error. Should it be accepted? Explain.

Explain which evidence supports your conclusion and which claim remains unproved.

11. Connect your project

Add a labelled dictionaries and records evidence sheet to Python readiness portfolio. Show how you can read and update named dictionary fields. Use the supplied fictional case and keep its inputs, intermediate steps, calculation or prediction, and limitation. Connect this record to last week's record; a matching answer without a trace is insufficient.

Project evidence · Record

Project evidence: Component and version

Record: _____

Project evidence: Inputs permitted at prediction time

Record: _____

Project evidence: Trace and comparison with earlier work

Record: _____

Project evidence: Failure, limit and human review

Record: _____

Evidence for your project

For Python readiness before the Responsible Plant Classifier, retain a trace of the values, the predicted outputs and the changed-case explanation. Use actual Python 3 results to check the prediction after reasoning first.

12. Show what you know

Named fields reduce position mistakes but do not prove that a record is accurate. A capacity of 2 with used of 5 is representable in a dictionary and violates this schema.

A record has capacity 3 and used 4. It gives -1 spaces without an error. Should it be accepted? Explain.

A record has capacity 3 and used 4. It gives -1 spaces without an error. Should it be accepted? Explain.

My limited claim and a useful next check

13. Study a complete case

Complete evidence record

Follow the evidence

Step or case	Evidence	Meaning
--------------	----------	---------

Step or case: Read used

Evidence: 4

Meaning: $12 - 4 = 8$

Step or case: Update used

Evidence: 6

Meaning: $12 - 6 = 6$

Read each row from left to right and connect the evidence to the stated rule.

Follow the input through the stated procedure to its result. Cover the result first, predict it, then explain every intermediate step. The text/table accompanies the figure so the example can be read without colour.

My complete trace of the worked case

14. Try a new case independently

Independent case: Read, update and pass a dictionary record

Predict the three outputs and trace the named-field update. Explain why zero and a missing count produce different results. If the condition becomes if not count, which supplied record is first handled incorrectly?

```
def describe(record):  
    count = record.get("count")  
    if count is None:  
        return "missing"  
    return count  
  
record = {"count": 0}  
print(describe(record))  
  
record["count"] = 3  
print(describe(record))  
  
print(describe({}))
```

My independent explanation, trace and limits

Attempt this case before feedback. Record any help. Earlier examples below are further practice; a case already practised with feedback cannot establish fresh transfer.

Attempt this without hints

Create a Green record with capacity 15 and used 6. Pass its fields to remaining and store the result. Update used to 10 and repeat. Predict both results.

My independent procedure, result and limitation

Record support used: none, hint or teacher explanation. After feedback, a different case is needed to demonstrate independence.

Use feedback to improve

Attempt the independent case before hints. Record whether you worked alone, used a hint or followed a model. After feedback, fix the first unsupported step and explain why it changed. A later check uses a changed case, not a copied answer.

15. Your lesson route

Start with this question: A zero field is still present. A dictionary record describes a shelf. The program distinguishes missing data from an actual zero.

By the end, I can · How I will show it

By the end, I can: Read and update named dictionary fields

How I will show it: Explain the deciding step, show a trace or test, and state one limit.

By the end, I can: Connect a record to a function call

How I will show it: Explain the deciding step, show a trace or test, and state one limit.

By the end, I can: Distinguish missing fields from zero values

How I will show it: Explain the deciding step, show a trace or test, and state one limit.

Remember → watch and explain → try with help → investigate → try independently → keep project evidence. Your teacher may spread this lesson across several classes.

Keep your first prediction. Compare it with what the evidence shows and explain any change.

16. Finish and return

Close your notes. Explain this goal in your own words: Read and update named dictionary fields

My deciding step, evidence and one remaining question

If you are unsure, return to the worked picture and explain one arrow. If you are ready, change an input or assumption and justify your prediction.

Save your workbook evidence. At the next review, try a different case before opening your old answer.
